spatialkernel-package The Spatialkernel Package

Description

An R package for spatial point process analysis.

Details

This package contains functions for spatial point process analysis using kernel smoothing methods. This package has been written to be compatible with the **splancs** package which is available on *CRAN* (The Comprehensive R Archive Network).

For a complete list of functions with individual help pages, use library (help = \ "spatialkernel").

Maintainer

Pingping Zheng pingping.zheng@lancaster.ac.uk>

Note

For the convience of the user, we present here examples which show how to use some of the functions in the package.

    z=lam, add=TRUE, breaks=brks, col=risk.colors(length(brks)-1))
polygon(polyb)
metre(0, 0.01, 0.05, 0.51, lab=brks, col=risk.colors(length(brks)-1), cex=1)
## An example of inhomogeneous intensity function and K function
## estimated with the same data
s \leftarrow seq(0, 0.06, length=101)
lam <- lambdahat(pts, hcv, poly=polyb)$lambda</pre>
kin <- kinhat(pts, lam, polyb, s)</pre>
plot(kin$s, kin$k-pi*(kin$s)^2, xlab="s", ylab="k-pi*s^2", type="l")
## End(Not run)
```

4 cvloglk

Description

Calculate the area of a polygon and its boundary direction.

Usage

```
areapoly(poly)
```

Arguments

matrix containing the x, y-coordinates of the vertices of the polygon boundary. poly

Value

area	positive numeric, the area of the polygon.
sign	integer, 1 if the polygon orientation is anticlockwise, -1 otherwise.
poly	copy of the passed argument poly.

Note

This function is provided here so that users do not need to load other packages, as it is not available in the base R packages.

References

Joseph O'Rourke, Computational Geometry in C (2nd Edition), Cambridge University Press, 2000 edition.

cvloglk	Cross-Validated Log-Likelihood Function
---------	---

Description

Calculate the cross-validated log-likelihood function.

Usage

```
cvloglk(pts, marks, t = NULL, h)
```

Arguments

pts	matrix containing the x, y-coordinates of the point locations.
marks	numeric/character vector of the marked labels of the type of each point.
t	numeric vector of the associated time-periods, default NULL for pure spatial data.
h	numeric vector of the kernel smoothing bandwidths at which to calculate the cross-validated log-likelihood function.

data 5

Details

Select a common bandwidth for kernel regression estimation of type-specific probabilities of a multivariate Poisson point process with independent component processes of each categorical type by maximizing the cross-validate log-likelihood function.

Select a common bandwidth for kernel regression of type-specific probabilities for all time-periods when the argument t is not NULL, in which case the data is of a multivariate spatial-temporal point process, with t the values of associated time-periods.

Value

A list with components

cv vector of the values of the cross-validated Log-likelihood function.

hcv numeric value which maximizing the cross-validate log-likelihood function

... copy of the arguments pts, marks, h.

data

Lansing Woods Trees

Description

This is the Lansing Woods Tree data set and an arbitrary polygon boundary within unit square.

Usage

```
data(lansing)
data(polyb)
```

Format

lansing is an R data. frame with x, y, marks and polyb is an R matrix with x, y.

Note

The Lansing Woods tree data set and the arbitrary polygon are provided here for the demonstration of the basic usage of this package. See Section **Examples** in spatialkernel-package.

6 filled.contour.poly

Source

Lansing Woods trees from Lansing Woods, Clinton County, Michigan USA, including hickories, maples, and oaks.

References

Gerrard, D.J. (1969) Competition quotient: a new measure of the competition affecting individual forest trees. *Research Bulletin* 20, Agricultural Experiment Station, Michigan State University.

filled.contour.poly Level (Contour) Plots with Polygonal Boundary

Description

This is a revised version of the **base** R function filled.contour. It additionally plots a polygonal boundary.

Usage

```
filled.contour.poly(x = seq(min(poly[,1]), max(poly[,1]),
  len = nrow(z)),
y = seq(min(poly[,2]), max(poly[,2]), len = ncol(z)),
z, poly,
xlim = range(x, finite=TRUE),
ylim = range(y, finite=TRUE),
zlim = range(z, finite=TRUE),
levels = pretty(zlim, nlevels), nlevels = 10,
color.palette = risk.colors,
col = color.palette(length(levels) - 1),
llevels = levels, labels = NULL, labcex = 0.6,
drawlabel = TRUE, method = "flattest",
vfont = c("sans serif", "plain"),
lcol = par("fg"), lty = par("lty"), lwd = par("lwd"),
plot.title, plot.axes, key.title, key.axes,
asp = NA, xaxs = "i", yaxs = "i", las = 1, axes = TRUE,
...)
```

Arguments

х,у	locations of grid lines at which the values in z are measured. These must be in ascending order. By default, equally spaced values from 0 to 1 are used. If x is a list, its components x\$x and x\$y are used for x and y, respectively. If the list has component z this is used for z.
Z	a matrix containing the values to be plotted (NAs are allowed). Note that x can be used instead of z for convenience.
xlim	x limits for the plot.

filled.contour.poly 7

ylim	y limits for the plot.
zlim	z limits for the plot.
poly	a matrix containing the x, y-coordinates of the vertices of the polygon boundary.
levels	a set of levels which are used to partition the range of z. Must be strictly increasing (and finite). Areas with z values between consecutive levels are painted with the same color.
nlevels	if levels is not specified, the range of z is divided into approximately this many levels.
color.palette	a color palette function used to assign colors in the plot.
col	an explicit set of colors to be used in the plot. This argument overrides any palette function specification.
llevels	numeric vector of levels at which to draw contour lines, default is the same as levels.
labels	a vector giving the labels for the contour lines. If NULL then the levels are used as labels.
labcex	cex for contour labelling.
drawlabel	logical, contour lines are labelled if TRUE.
method	character string specifying where the labels will be located. Possible values are "simple", "edge" and "flattest" (the default). See the Details section.
vfont	if a character vector of length 2 is specified, then Hershey vector fonts are used for the contour labels. The first element of the vector selects a typeface and the second element selects a fontindex (see text for more information).
lcol	color for the lines drawn.
lty	line type for the lines drawn.
lwd	line width for the lines drawn.
plot.title	statement which add title to the main plot.
plot.axes	statement which draws axes on the main plot. This overrides the default axes.
key.title	statement which adds title to the plot key.
key.axes	statement which draws axes on the plot key. This overrides the default axis.
asp	the y/x aspect ratio, see plot.window.
xaxs	the x axis style. The default is to use internal labeling.
yaxs	the y axis style. The default is to use internal labeling.
las	the style of labeling to be used. The default is to use horizontal labeling.
axes,	additional graphical parameters.

Note

By defining z values as NA at points outside the polygonal boundary, filled.contour.poly produces a contour plot within the polygonal boundary.

filled.contour, contour and pinpoly

8 kinhat

kinhat	Inhomogeneous K-function Estimation	

Description

Estimate the inhomogeneous K function of a non-stationary point pattern.

Usage

```
kinhat(pts, lambda, poly, s)
```

Arguments

pts matrix of the x,y-coordinates of the point locations.

lambda intensity function evaluated at the above point locations.

poly matrix of the x,y-coordinates of the polygon boundary.

s vector of distances at which to calculate the K function.

Details

The inhomogeneous K function is a generalization of the usual K function defined for a second-order intensity-reweighted stationary point process, proposed by Baddeley $et \land al$ (2000).

When the true intensity function is unknown, and is to be estimated from the same data as been used to estimate the K function, a modified kernel density estimation implemented in lambdahat with argument gpts=NULL can be used to calculate the estimated intensity at data points. See Baddeley *et al* (2000) for details, and Diggle, P.J., *et al* (2006) for a cautious note.

Value

A list with components

k values of estimated K at the distances s.

s copy of s.

Note

This code is adapted from **splancs** (Rowlingson and Diggle, 1993) fortran code for the estimation of homogeneous K function khat, with edge correction inherited for a general polygonal area.

khat, lambdahat

lambdahat Kernel Density Estimation of Intensity Function

Description

Kernel density estimation of the intensity function of a two-dimensional point process.

Usage

```
lambdahat(pts, h, gpts = NULL, poly = NULL, edge = TRUE)
```

Arguments

pts	matrix containing the x, y-coordinates of the data point locations.
h	numeric value of the bandwidth used in the kernel smoothing.
gpts	matrix containing the x,y-coordinates of point locations at which to calculate the intensity function, usually a fine grid points within poly, default NULL to estimate intensity function at data locations.
poly	matrix containing the x , y -coordinates of the vertices of the polygon boundary in an anticlockwise order.
edge	logical, with default TRUE to do edge-correction.

Details

Kernel smoothing methods are widely used to estimate the intensity of a spatial point process. One problem which arises is the need to handle edge effects. Several methods of edge-correction have been proposed. The adjustment factor proposed in Berman and Diggle (1989) is a double integration $\int_A K[(x-x_0)/h]/h^2$, where A is a polygonal area, K is the smoothing kernel and h is the bandwidth used for the smoothing. Zheng, P. $e \wedge al$ (2004) proposed an algorithm for fast calculate of Berman and Diggle's adjustment factor.

When gpts is NULL, lambdahat uses a leave-one-out estimator for the intensity at each of the data points, as been suggested in Baddeley *et al* (2000). This leave-one-out estimate at each of the data points then can be used in the inhomogeneous K function estimation kinhat when the true intensity function is unknown.

The default kernel is the *Gaussian*. The kernel function is selected by calling setkernel.

Value

A list with components

```
numeric vector of the estimated intensity function.copy of the arguments pts, gpts, h, poly, edge.
```

10 mcpat.test

Note

In principle, the *double adaptive* double integration algorithm of Zheng, P. *et\ al* (2004) can be applied to other kernel functions.

Other source codes used in the implementation of the double integration algorithm include

- Laurie, D.P. (1982) adaptive cubature code in Fortran;
- Shewchuk, J.R. triangulation code in C;
- Alan Murta's polygon intersection code in C (Project: Generic Polygon Clipper).

mcpat.test

Monte Carlo Inference of Temporal Changes in Spatial Segregation

Description

An approximate Monte Carlo test of temporal changes in a multivariate spatial-temporal point process.

Usage

```
mcpat.test(pts, marks, t, h, ntest = 100, proc = TRUE)
```

mcpat.test 11

Arguments

pts	matrix containing the x, y-coordinates of the data point locations.
marks	numeric/character vector of the marked type labels of the data points.
t	numeric vector of the associated time-periods.
h	numeric vector of the bandwidths at which to calculate the cross-validated log-likelihood function pooled over times.
ntest	integer with default 100, number of simulations for the Monte Carlo test
proc	logical, default TRUE prints the processing messages.

Details

The spatial-temporal data are denoted as (x_i, m_i, t_i) , where x_i are the spatial locations, m_i are the categorical mark sequence numbers, and t_i are the associated time-periods.

The null hypothesis is that the type-specific probability surfaces are constant over time-periods, i.e., $p_k(x,t) = p_k(x)$, for any t, where $p_k(x,t)$ are the type-specific probabilities for kth category within time-period t.

Each Monte Carlo simulation is sampled from an approximate *true* type-specific probability surfaces — the estimated one from the data. Approximately, the simulated data and the original data are samples from the same probability distribution under the null hypothesis. See Diggle, P.J. *et al* (2005) for more details.

Value

A list with components

```
pvalue p-value of the approximate Monte Carlo test. ... copy of pts, marks, t, h, ntest.
```

References

1. Diggle, P. J. and Zheng, P. and Durr, P. A. (2005) Nonparametric estimation of spatial segregation in a multivariate point process: bovine tuberculosis in Cornwall, UK. *J. R. Stat. Soc. C*, **54**, 3, 645–658.

12 mcseg.test

mcseg.test	Monte Carlo Test of Spatial Segregation in Multivariate Point Process

Description

Monte Carlo test of spatial segregation in a multivariate point process by simulating data from random re-labelling of the categorical marks.

Usage

```
mcseg.test(pts, marks, h, stpts = NULL, ntest = 100,
    proc = TRUE)
```

Arguments

pts	matrix containing the x, y-coordinates of the data point locations.
marks	numeric/character vector of the marked type labels of the point pattern.
h	numeric vector of the bandwidths at which to calculate the cross-validated likelihood function.
stpts	matrix containing the x , y -coordinates of the locations at which to implement the pointwise segregation test, with default NULL not to do the pointwise segregation test.
ntest	integer with default 100, number of simulations for the Monte Carlo test
proc	logical with default TRUE to print the processing messages.

Details

The null hypothesis is that the estimated risk surface is spatially constant, *i.e.*, the type-specific probabilities are $p_k(x) = p_k$, for all k, see phat. Each Monte Carlo simulation is done by relabeling the data categorical marks at random whilst preserving the observed number of cases of each type.

The segregation test can also be done pointwise, usually at a fine grid of points, to mark the areas where the estimated type-specific probabilities are significantly greater or smaller than the spatial average.

Value

A list with components

pvalue	numeric, p-value of the Monte Carlo test.
stpvalue	matrix, p -values of the test at each point in stpts (if stpts is not NULL), with each column corresponds to one type
	copy of the arguments pts, marks, h, stpts, ntest, proc.

metre

Plot Color Level Metre

Description

This is a simple function provided here for the convenience of users. It adds a key showing how the colors map to the values of an image plot.

Usage

```
metre(xl, yb, xr, yt, lab, cols = risk.colors(length(lab) - 1),
shift = 0, cex = 1)
```

Arguments

xl,yb,xr,yt	x,y coordinates of the left-bottom and right-top corners of the color level metre bar.
lab	metre level labels in the metre.
cols	associated colours, defaults to use risk.colors.
shift	distance to shift the label texts away from the metre bar.
cex	numeric character expansion factor.

See Also

risk.colors

phat phat

package.version

Listing Loaded/Installed Package Versions

Description

List version numbers of loaded or installed packages.

Usage

```
package.version(all.available = FALSE, lib.loc = NULL)
```

Arguments

all.available logical, if TRUE return all available packages.

lib.loc character vector describing the location of R library trees to search through, or

NULL. The default value of NULL corresponds to all libraries currently known.

Details

This is a revised version of the base R function .package. It gives both package names and their version numbers.

Value

A list with components

package names of loaded or available packages if all.available is TRUE.

version associated package versions.

.packages

phat

Estimate Type-Specific Probabilities

Description

Estimate the type-specific probabilities for a multivariate Poisson point process with independent component processes of each type.

Usage

```
phat(gpts, pts, marks, h)
```

pinpoly 15

Arguments

gpts	matrix containing the x,y-coordinates of the point locations at which type- specific probabilities are estimated.
pts	matrix containing the x, y-coordinates of the data points.
marks	numeric/character vector of the types of the point in the data.
h	numeric value of the bandwidth used in the kernel regression.

Details

The type-specific probabilities for data (x_i, m_i) , where x_i are the spatial point locations and m_i are the categorical mark sequence numbers, $m_i = 1, 2, \ldots$, are estimated using the kernel smoothing methodology $\hat{p}_k(x) = \sum_{i=1}^n w_{ik}(x) I(m_i = k)$, where $w_{ik}(x) = w_k(x - x_i) / \sum_{j=1}^n w_k(x - x_j)$, $w_k(.)$ is the kernel function with bandwidth $h_k > 0$, $w_k(x) = w_0(x/h_k)/h_k^2$, and $w_0(\cdot)$ is the standardised form of the kernel function.

The default kernel is the *Gaussian*. Different kernels can be selected by calling setkernel.

Value

A list with components

matrix of the type-specific probabilities for all types, with the type marks as the matrix row names.
copy of the arguments pts, dpts, marks, h.

References

1. Diggle, P. J. and Zheng, P. and Durr, P. A. (2005) Nonparametric estimation of spatial segregation in a multivariate point process: bovine tuberculosis in Cornwall, UK. *J. R. Stat. Soc. C*, **54**, 3, 645–658.

See Also

```
cvloglk, mcseg.test, and setkernel.
```

pinpoly Check if Points are within Polygon

Description

Check the location of point(s) with respect to a polygon.

Usage

```
pinpoly(poly, pts)
```

16 risk.colors

Arguments

poly	matrix containing the x,y-coordinates of the vertices of the polygon boundary.
pts	matrix of containing the x,y-coordinates of the point locations.

Value

An integer vector of indicators for each point in pts,

-1 error when number of polygon vertices exceeds 3000;

0 outside the polygon;

1 at the polygon boundary;

2 inside the polygon.

Note

This function is provided here so that users do not need to load other packages, as it is not available in the **base** R packages.

The return values have been changed from the original ones so that the point is inside (including at the boundary) if positive.

References

```

risk.colors

Color Palette

Description

This color palette is designed to show risk levels with different colours from small risk (bright orange) to high risk (dark red).

Usage

```
risk.colors(n)
```

Arguments

n number of colors (≥ 1) to be in the palette.

setkernel 17

See Also

```
metre, colors, and palette.
```

Examples

```
## risk pie with ten levels
pie(rep(1,10), labels = seq(0.1, 1, 0.1), col = risk.colors(10))
```

setkernel

Select Smoothing Kernel Function

Description

Select a kernel function for kernel regression and kernel smoothing.

Usage

```
setkernel(kernel = NULL)
```

Arguments

kernel

character string giving the smoothing kernel to be used. This must be one of *gaussian*, *epanechnikov*, *quadratic*, *quartic*, or NULL, and may be abbreviated to a unique prefix.

Value

A character string of the kernel function selected, or the kernel function currently being used when kernel is NULL.

Note

The default kernel used is *Gaussian*. Unless users want to use a non-default kernel, there is no need to call setkernel. *quadratic* is an alias for *epanechnikov*.

setkernel setup kernel function for both kernel regression in the type-specific probability estimation and the kernel smoothing in the intensity function estimation.

See Also

```
cvloglk, phat and lambdahat
```

Examples

```
## Not run:
    setkernel("e") ## Select "epanechnikov" kernel
    setkernel() ## show the kernel currrently being used
## End(Not run)
```

18 spseg

spseg

Integrated Functions for Spatial Segregation Analysis

Description

Spatial segregation analysis to be performed by a single function and presentations by associated plot functions.

Usage

```
spseg(pts, marks, h, opt = 2, ntest = 100, poly = NULL,
    delta = min(apply(apply(pts, 2, range), 2, diff))/100,
proc = TRUE)
    plotcv(obj, ...)
    plotphat(obj, types = unique(obj$marks), sup = TRUE,
        col = risk.colors(10),
breaks = seq(0, 1, length = length(col) + 1), ...)
    plotmc(obj, types = unique(obj$marks), quan = c(0.05, 0.95),
        sup = FALSE, col = risk.colors(10),
breaks = seq(0, 1, length = length(col) + 1), ...)
```

Arguments

pts	matrix containing the x,y-coordinates of the point locations at which type-specific probabilities estimated.
marks	numeric/character vector of the types of the point in the data.
h	numeric vector of the kernel smoothing bandwidth at which to calculate the cross-validated log-likelihood function.
opt	integer, 1 to select bandwidth; 2 to calculate type-specific probabilities; and 3 to do the Monte Carlo segregation test.
ntest	integer with default 100, number of simulations for the Monte Carlo test.
poly	matrix containing the x, y-coordinates of the polygonal boundary of the data.
delta	spacing distance of grid points at which to calculate the estimated type-specific probabilities for image plot.
proc	logical with default TRUE to print the processing message.
obj	list of the returning value of spseg
types	numeric/character types of the marks of data points to plot the estimated type- specific probabilities, default to plot all types.
sup	logical with default FALSE, if TRUE to superimpose data points on the estimated type-specific probability surface.
quan	numeric, the pointwise significance levels to add contours to image plot of the estimated type-specific probability surface, with default of c(0.05, 0.95).
col	list of colors such as that generated by risk.colors.
breaks	a set of breakpoints for the col: must give one more breakpoint than colour.
	other arguments concerning plot and points

spseg 19

Details

spseg implements a complete spatial segregation analysis by selecting bandwidth, calculating the type-specific probabilities, and then carrying out the Monte Carlo test of spatial segregation and pointwise significance. Some plot functions are also provided here so that users can easily present the results.

These functions are provided only for the convenience of users. Users can instead use individual functions to implement the analysis step by step and plot the diagrams as they wish.

Examples of how to use spseg and present results using plot functions are presented in spatialkernel-package.

Value

spseg returns a list with components

hcv bandwidth selected by the cross-validated log-likelihood function.

gridx, gridy x, y coordinate vectors at which the grid points are generated at which to cal-

culate the type-specific probabilities and pointwise segregation test *p*-value.

p estimated type-specific probabilities at grid points generated by vectors gridx, gridy.

p-value of the Monte Carlo spatial segregation test.

stpvalue pointwise *p*-value of the Monte Carlo spatial segregation test.

... copy of pts, marks, h, opt.

Note

Setting h to a unique value may force spseg to skip the selecting bandwidth step, go straight to calculate the type-specific probabilities and then test the spatial segregation with this fixed value of bandwidth.
